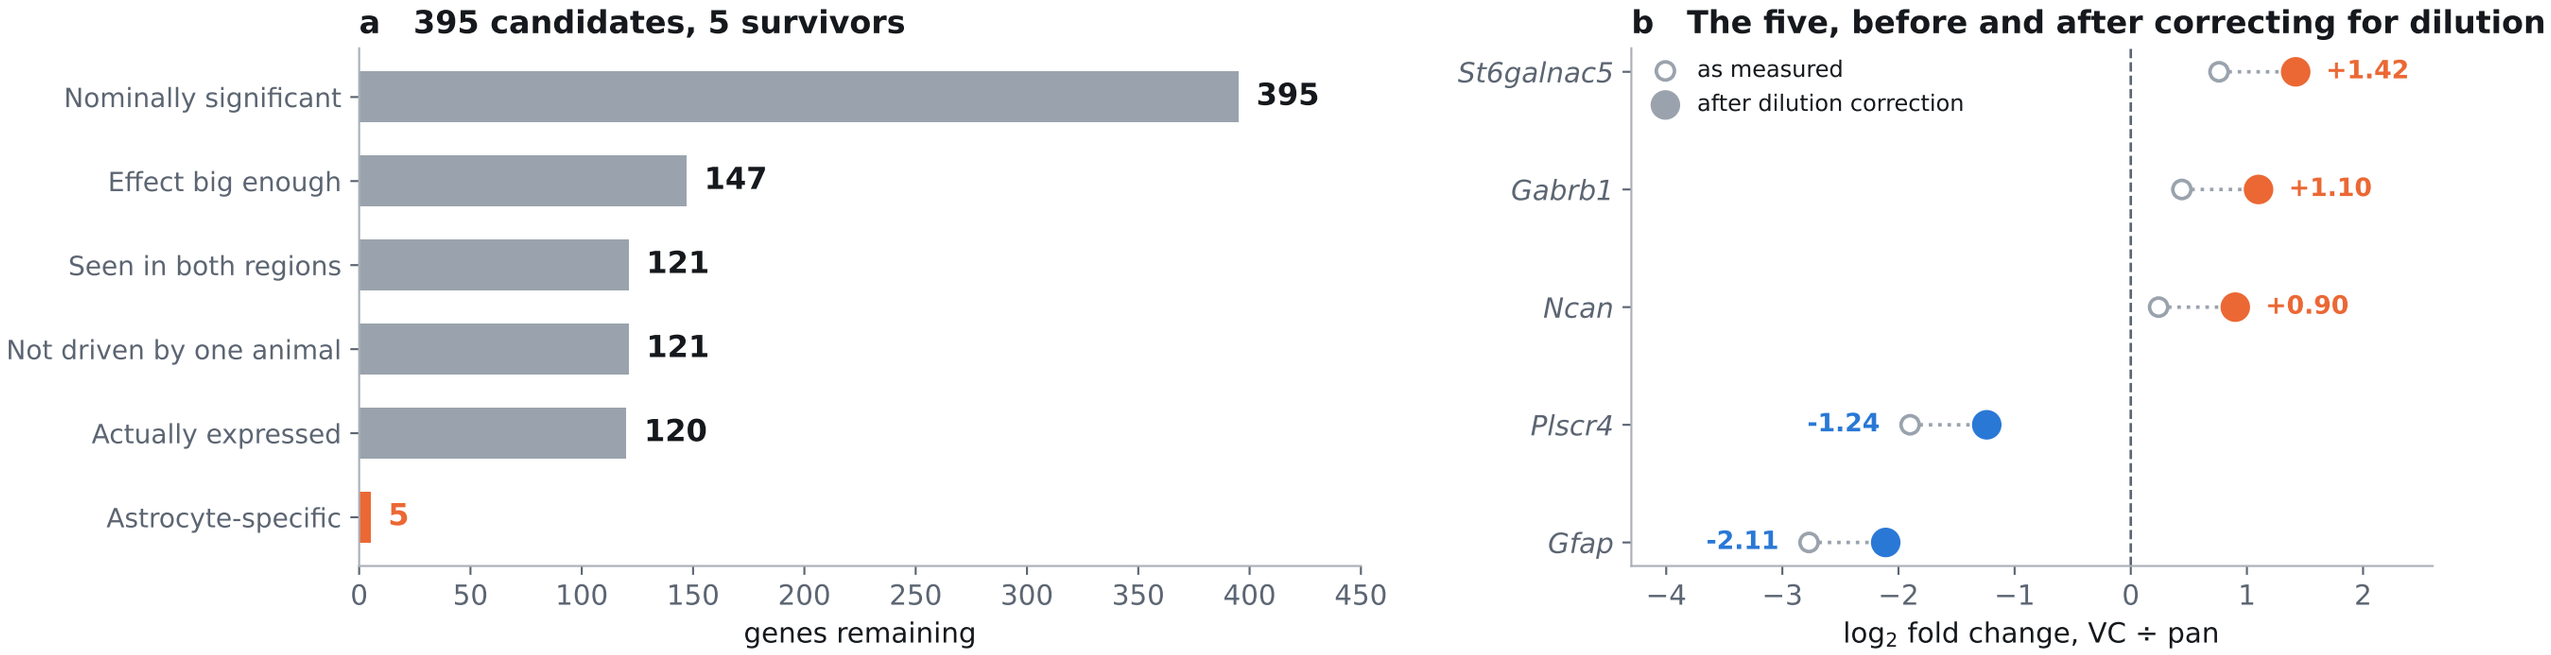
Correcting for dilution leaves five interpretable genes



Filters, in order: moderated test FDR < 0.05 · dilution-corrected |Δ| ≥ 1 · same direction in cortex and striatum · stable across 16 leave-one-out fits · ≥ 50 counts · astrocyte-specific in the snRNA-seq reference.
a: counts from the upstream analysis. b: fold changes from the supplied striatal table, corrected by subtracting the −0.66 astrocyte-dilution offset. Ncan does not reach significance on its own (FDR 0.57).
